Lobue & DeLoache (2008)
Data screening & Cleanup

Two data files are included: an Excel file including the raw data populated by our program and an SPSS file that is clean and ready for analysis.

A few explanatory notes about these files:

Regarding the Excel file:

1. Only the 24 test trials were included (no reaction times for practice trials were recorded).
2. Upon touching the screen, 2 pieces of information were entered
    a. Picture selection. Each picture was numbered and included a "s" for snake or "c" for caterpillar. This allowed us to determine whether the correct target image was selected. These columns were removed in the final file.
    b. Reaction time. As our DV, these columns were maintained for the final file. Reaction times of incorrect responses were removed and treated as missing data.
3. Some participants recorded more than 24 selections and reaction times. When participants (primarily children) touched or tapped the screen more than once to indicate their selection, at times, multiple responses were recorded. These duplicates were easily found and the first reaction time was retained while subsequent reaction times were removed.
4. This file includes all participants, even those subsequently removed as outliers or due to a high percentage of incorrect answers.

Regarding SPSS:

1. Demographic information was collected separately and entered manually.
2. Some children's parents did not participate. Thus, demographic information is not available for all child participants.
3. There are adult cases that include both the parent's and the child's demographic information (for example, ID 2009A). These are reported in this way only for cases in which the child was removed from analysis.
4. The stimulus condition was entered manually into the program that populated our excel file—this was maintained in the final file and additional variables were created to recode "A"s and "B"s as "1"s and "2"s.
